Sample Animal Physiology Exam Questions with Answers

Question 1: Multiple Choice

Q: Which of the following hormones is primarily responsible for regulating blood calcium levels?

- A) Insulin
- B) Parathyroid hormone
- C) Calcitonin
- D) Glucagon

Answer: B) Parathyroid hormone

Explanation: Parathyroid hormone (PTH) increases blood calcium levels by stimulating bone resorption, increasing intestinal calcium absorption, and reducing calcium excretion by the kidneys. Calcitonin, on the other hand, lowers blood calcium levels.

Question 2: Short Answer

Q: Describe the process of synaptic transmission across a neuron.

Answer:

Synaptic transmission involves the transfer of nerve impulses from one neuron to another across a synapse. When an action potential reaches the presynaptic terminal, it triggers the opening of voltage-gated calcium channels. Calcium ions enter the neuron, prompting synaptic vesicles to fuse with the presynaptic membrane and release neurotransmitters into the synaptic cleft. These neurotransmitters bind to specific receptors on the postsynaptic neuron, leading to the opening of ion channels that generate a new action potential if the threshold is reached. The process is terminated by neurotransmitter reuptake, enzymatic degradation, or diffusion.

Question 3: Essay Question

Q: Explain the process of muscle contraction in vertebrates.

Answer:

Muscle contraction in vertebrates occurs through the sliding filament mechanism, involving the

interaction of actin and myosin filaments within muscle fibers. Upon stimulation by a nerve impulse, calcium ions are released from the sarcoplasmic reticulum into the cytoplasm. Calcium binds to troponin, causing a conformational change that moves tropomyosin away from the myosin-binding sites on actin filaments. This allows myosin heads, energized by ATP hydrolysis, to bind to actin forming cross-bridges. The myosin heads then pivot, pulling the actin filaments toward the center of the sarcomere—a process known as the power stroke. ATP binding to myosin causes detachment from actin, and the cycle repeats as long as calcium ions remain elevated. Relaxation occurs when calcium is pumped back into the sarcoplasmic reticulum, and the filaments slide back to their resting positions.

Question 4: Problem-Solving

Q: An animal consumes oxygen at a rate of 150 mL/min. If the animal's body weight is 10 kg, calculate its oxygen consumption per kg per hour.

Answer:

First, convert oxygen consumption to per hour:

$$150 \text{ mL/min} \times 60 \text{ min} = 9000 \text{ mL/hour}$$

Now, divide by body weight:

$$9000 \text{ mL/hour} \div 10 \text{ kg} = 900 \text{ mL/kg/hour}$$

Final answer: The animal consumes 900 mL of oxygen per kilogram of body weight per hour.

Sample Exam Questions with Detailed Answers

Below are more comprehensive examples illustrating different question types and detailed explanations.

Question 1: Explain the process of thermoregulation in mammals and identify key physiological mechanisms involved.

Answer:

Thermoregulation in mammals involves maintaining internal body temperature within a narrow optimal range. Key mechanisms include:

- Vasodilation and Vasoconstriction: Adjusting blood flow to the skin to dissipate or conserve heat.
- Sweating: Evaporative cooling through sweat glands.
- Shivering: Involuntary muscle contractions generate heat when cold.

Answer:

The nephron is the functional unit of the kidney responsible for filtering blood and forming urine. It consists of structures such as the glomerulus, proximal tubule, loop of Henle, distal tubule, and collecting duct.

Process of urine formation involves:

- Filtration: Blood enters the glomerulus; water and small solutes are filtered into Bowman's capsule.
- Reabsorption: Essential substances like glucose, ions, and water are reabsorbed back into the bloodstream in the proximal tubule.
- Secretion: Additional waste products and ions are secreted into the tubule.
- Concentration: The Loop of Henle creates a concentration gradient, enabling the kidney to produce concentrated urine.
- Excretion: Final urine, containing waste and excess substances, is collected in the collecting duct and excreted via the ureter.

This process maintains fluid and electrolyte balance and removes metabolic wastes.

Conclusion

Animal physiology exam questions with answers form a cornerstone of effective learning and assessment. They enable students to test their knowledge, understand complex concepts, and develop critical thinking skills necessary for mastery in the field. Whether through multiple-choice questions, short answers, or detailed essays, each format offers unique advantages tailored to different learning objectives. QuestionAnswer What are the primary functions of the circulatory system in animals? The

primary functions of the circulatory system in animals include transporting nutrients, oxygen, and hormones to cells, removing waste products, and maintaining homeostasis by regulating temperature and pH levels. How do different animal species adapt their respiratory systems to their environments? Animals adapt their respiratory systems based on their habitats; for example, aquatic animals like fish use gills for extracting oxygen from water, while terrestrial animals have lungs to breathe air. Some amphibians can also absorb oxygen through their skin, and certain species have specialized structures to survive in low-oxygen environments. Explain the process of muscle contraction in animals. Muscle contraction occurs when the nervous system stimulates muscle fibers, causing the release of calcium ions inside the muscle. This triggers the interaction between actin and myosin filaments, leading to the sliding filament mechanism that shortens the muscle and produces contraction. What is the role of the kidneys in animal physiology? The kidneys regulate water and electrolyte balance, remove waste products from the blood through filtration, and help control blood pressure. They also play a crucial role in maintaining acid-base balance and producing hormones such as erythropoietin. Describe how thermoregulation is achieved in endothermic animals. Endothermic animals maintain a stable internal body temperature through metabolic heat production and heat conservation mechanisms such as vasoconstriction, shivering, and behavioral adaptations like seeking shade or basking to dissipate or generate heat as needed. What are the differences between the nervous and endocrine systems in animal physiology? The nervous system provides rapid, short-term responses to stimuli through electrical signals and nerve impulses, while the endocrine system regulates longer-term processes via hormones released into the bloodstream, affecting various tissues and organs over time.

Sample Questions and Detailed Answers from 2014

To illustrate the depth and scope of the 2014 exam, here are select questions with comprehensive explanations:

Question 1: Cell Structure and Functions

Describe the main differences between a plant cell and an animal cell. Use diagrams to support your answer.

Answer:

Feature	Plant Cell	Animal Cell
Cell Wall	Present; made of cellulose, provides rigidity	Absent
Chloroplasts	Present; contain chlorophyll for photosynthesis	Absent
Vacuole	Large central vacuole, maintains turgor pressure	Small or absent
Shape	Usually rectangular or fixed shape	Irregular and flexible
Centrioles	Usually absent in mature plant cells; present in animal cells	Present

Explanation:

Plant cells have a rigid cell wall and chloroplasts, enabling photosynthesis and structural support. Animal cells lack these features but contain centrioles involved in cell division. The large central vacuole in plant cells stores water and maintains shape, whereas animal cells have smaller vacuoles or none.

Question 2: Human Circulatory System

Explain the pathway of blood through the human heart, including the chambers involved.

Answer:

Blood flow through the heart follows this sequence:

- Deoxygenated blood from the body enters the right atrium via the vena cava.
- The right atrium contracts, pushing blood through the atrioventricular (tricuspid) valve into the right ventricle.
- The right ventricle contracts, pumping blood through the pulmonary valve into the pulmonary arteries.
- Blood is transported to the lungs for oxygenation.

- Oxygenated blood returns to the left atrium via the pulmonary veins.
- The left atrium contracts, sending blood through the bicuspid (mitral) valve into the left ventricle.
- The left ventricle contracts powerfully, pumping blood through the aortic valve into the aorta, distributing it to the body.

Key Point: The heart's chambers work in a coordinated manner to ensure unidirectional blood flow, with valves preventing backflow.

Question 3: Photosynthesis Process

Describe the process of photosynthesis, including the raw materials and the end products.

Answer:

Photosynthesis is the process by which green plants convert light energy into chemical energy. It occurs mainly in the chloroplasts of leaf cells.

Raw materials:

- Carbon dioxide (CO₂) from the atmosphere
- Water (H₂O) absorbed by roots
- Light energy from the sun

Process steps:

- Light absorption by chlorophyll triggers the conversion of light energy into chemical energy.
- The energy splits water molecules (photolysis), releasing oxygen (O₂) as a byproduct.
- The Calvin cycle uses ATP and NADPH produced in the light-dependent reactions to fix CO₂ into glucose.

End products:

- Glucose (C₆H₁₂O₆), which serves as energy and building material
- Oxygen (O₂), released into the environment

Significance: Photosynthesis is vital for life on Earth, providing oxygen and organic compounds.
