This article aims to provide comprehensive insights into Chapter 17 thermochemistry, including common questions, detailed explanations, and tips for mastering the subject matter.

Understanding Thermochemistry in Chapter 17

Thermochemistry focuses on the heat involved in chemical processes. It investigates how energy flows during reactions, whether as heat absorbed or released, and how these processes relate to the overall energy changes within a system.

Key Concepts in Chapter 17

- Enthalpy (ΔH): The heat content of a system at constant pressure.
- Exothermic and Endothermic Reactions: Reactions that release or absorb heat, respectively.
- Heat Capacity and Specific Heat: The amount of heat needed to raise the temperature of a substance.
- Calorimetry: The experimental measurement of heat transfer.
- Hess's Law: The principle that total enthalpy change is the same regardless of the pathway taken.
- Standard Enthalpy of Formation: The change in enthalpy when one mole of compound forms from its elements in their standard states.

Common Assessment Questions and Their Answers

Assessment questions in Chapter 17 often test students' understanding of concepts through calculation, conceptual explanations, and application-based problems.

1. What is the difference between an exothermic and an endothermic reaction?

Answer:

An exothermic reaction releases heat into the surroundings, resulting in a temperature increase. Examples include combustion reactions and neutralization reactions. Conversely, an endothermic reaction absorbs heat from the surroundings, leading to a temperature decrease. Examples include melting ice and photosynthesis. The key distinction lies in the direction of heat flow: exothermic reactions have a negative ΔH , while endothermic reactions have a positive ΔH .

2. How do you calculate the heat absorbed or released during a process?

Answer:

The heat transfer (q) during a process can be calculated using the formula:

$$[q = mc\Delta T]$$

where:

- m = mass of the substance
- c = specific heat capacity of the substance
- ΔT = change in temperature (final - initial)

For reactions involving a known enthalpy change per mole, use:

$$[q = n \times \Delta H]$$

where n is the number of moles reacting or produced.

3. Explain Hess's Law and provide an example of its application.

Answer:

Hess's Law states that the total enthalpy change for a chemical reaction is the same regardless of the pathway taken, provided the initial and final states are the same. This allows us to calculate enthalpy changes that are difficult to measure directly by combining known reactions.

Example:

Calculate the enthalpy change for the formation of CO_2 from C and O_2 , given the following data:

Using Hess's Law:

$$\Delta H = \Delta H_f^\circ + \Delta H_c^\circ = (-110.5) + (-283.0) = -393.5 \text{ kJ}$$

4. How do you determine the standard enthalpy of formation for a compound?

Answer:

The standard enthalpy of formation (ΔH_f°) is determined experimentally through calorimetry or calculated using Hess's Law and known enthalpies of reactions. It represents the heat change when one mole of a compound forms from its elements in their standard states at 25°C and 1 atm. Values are tabulated and used to compute overall reaction enthalpies.

5. What is the significance of calorimetry in thermochemistry?

Answer:

Calorimetry is a technique used to measure the heat transfer during physical or chemical changes. It provides experimental data necessary for calculating enthalpy changes, understanding reaction energetics, and verifying theoretical predictions. Common calorimeters include coffee cup calorimeters for aqueous reactions and bomb calorimeters for combustion reactions.

Assessment Answers and Their Application

The answers provided in Chapter 17 assessments often address common question types: multiple-choice, short answer, calculations, and conceptual explanations. Here, we analyze these answers in detail.

1. Calculating Enthalpy Changes from Calorimetry Data

Sample Question:

A 50.0 g sample of water is heated from 25°C to 80°C. Calculate the heat absorbed during this process.

Typical Answer Breakdown:

- Use the formula: $q = mc\Delta T$
- Given:
 - $m = 50.0 \text{ g}$
 - $c = 4.18 \text{ J/g}^\circ\text{C}$ (specific heat capacity of water)
 - $\Delta T = 80^\circ\text{C} - 25^\circ\text{C} = 55^\circ\text{C}$

Calculation:

$$q = 50.0 \text{ g} \times 4.18 \text{ J/g}^\circ\text{C} \times 55^\circ\text{C} = 50.0 \times 4.18 \times 55 = 11,495 \text{ J}$$

Assessment Insight:

- Correct application of calorimetry principles.
- Emphasizes the importance of units and temperature change.

2. Applying Hess's Law to Determine Enthalpy of Formation

Sample Question:

Given the following reactions:

- a) $\text{C(s)} + 2\text{H}_2\text{(g)} \rightarrow \text{CH}_4\text{(g)}$; $\Delta H = -74.8 \text{ kJ}$
- b) $\text{C(s)} + \text{O}_2\text{(g)} \rightarrow \text{CO}_2\text{(g)}$; $\Delta H = -393.5 \text{ kJ}$
- c) $\text{CH}_4\text{(g)} + 2\text{O}_2\text{(g)} \rightarrow \text{CO}_2\text{(g)} + 2\text{H}_2\text{O(l)}$; $\Delta H = -891.0 \text{ kJ}$

Calculate the standard enthalpy of formation of methane (CH_4).

Typical Answer Explanation:

- Recognize that the target reaction:

- Use Hess's Law by manipulating given reactions to sum to the target:
- Reaction (a): Formation of CH_4 from C and H_2
- Reaction (b): Combustion of C to CO_2
- Reaction (c): Combustion of CH_4 to CO_2 and H_2O

- Rearranged, the enthalpy of formation of CH_4 can be derived as:

$$\Delta H_f^\circ (\text{CH}_4) = \Delta H (b) + 2 \times \Delta H (c) - \Delta H (a)$$

- Substitute:

$\Delta H^\circ = (-393.5) + 2 \times (-891.0) - (-74.8) = -393.5 - 1782.0 + 74.8 = -2100.7 \text{ kJ}$ (which indicates a need for careful algebraic setup; actual calculations may vary based on reaction manipulation).

Assessment Tips:

- Properly balance reactions before combining.
- Understand the reversibility of reactions and sign conventions.
- The importance of systematic approach in applying Hess's Law.

3. Standard Enthalpy of Formation and Bond Energies

Sample Question:

$\text{C}_2\text{H}_2(\text{g}) + 3.5 \text{ O}_2(\text{g}) \rightarrow 2\text{CO}_2(\text{g}) + 3\text{H}_2\text{O}(\text{l})$, using bond energies.

Typical Answer Approach:

- List bond energies for reactants and products:
 - $\text{C}\equiv\text{C}$, $\text{C}\text{--}\text{H}$, $\text{C}=\text{O}$, $\text{O}=\text{O}$ bonds
- Calculate the total bond energies broken and formed:
 - Bonds broken: in C_2H_2 and O_2
 - Bonds formed: in CO_2 and H_2O
- Enthalpy change (ΔH) = (Sum of bonds broken) - (Sum of bonds formed)
- Example calculation:
 - Bonds broken: $\text{C}\equiv\text{C}$ (1), $\text{C}\text{--}\text{H}$ (6), $\text{O}=\text{O}$ (3.5)
 - Bonds formed: $\text{C}=\text{O}$ (4 in CO_2), $\text{O}\text{--}\text{H}$ (6 in H_2O)
- Final estimate involves summing these energies appropriately.

Common Types of Thermochemistry Assessment Questions and Their Answers

To illustrate the depth and utility of assessment answers, consider these common question types and their ideal solutions:

1. Calculating Enthalpy Change from Calorimetry Data

Question:

A 50.0 g sample of water is heated from 25.0°C to 80.0°C in a calorimeter. The temperature change recorded is 55.0°C. If the calorimeter's heat capacity is 200 J/°C, calculate the enthalpy change (ΔH) for the process.

Expert Answer:

Step 1: Calculate the heat absorbed by the water:

$$q_{\text{water}} = m \times c_{\text{water}} \times \Delta T$$

Where:

- $m = 50.0\text{ g}$
- $c_{\text{water}} = 4.18\text{ J/g}^\circ\text{C}$
- $\Delta T = 55.0^\circ\text{C}$

$$q_{\text{water}} = 50.0\text{ g} \times 4.18\text{ J/g}^\circ\text{C} \times 55.0^\circ\text{C} = 50.0 \times 4.18 \times 55.0$$

$$q_{\text{water}} = 50.0 \times 229.9 = 11,495\text{ J}$$

Step 2: Calculate the heat absorbed by the calorimeter:

$$q_{\text{calorimeter}} = C_{\text{calorimeter}} \times \Delta T = 200\text{ J/}^\circ\text{C} \times 55.0^\circ\text{C} = 11,000\text{ J}$$

Step 3: Total heat exchange:

$$q_{\text{total}} = q_{\text{water}} + q_{\text{calorimeter}} = 11,495\text{ J} + 11,000\text{ J} = 22,495\text{ J}$$

Step 4: Determine ΔH per mole of water:

- Moles of water:

$$n = \frac{50.0\text{ g}}{18.015\text{ g/mol}} \approx 2.78\text{ mol}$$

- Enthalpy change per mole:

$$\Delta H = \frac{q_{\text{total}}}{n} \approx \frac{22,495\text{ J}}{2.78\text{ mol}} \approx 8,088\text{ J/mol}$$

Final Answer:

The enthalpy change for heating the water is approximately +8.09 kJ/mol, indicating an endothermic process.

2. Using Hess's Law to Find Enthalpy Change

Question:

Given the following reactions:

- $\text{C(s)} + 2\text{H}_2\text{(g)} \rightarrow \text{CH}_4\text{(g)} \quad \Delta H_1 = -75\text{ kJ}$
- $\text{C(s)} + \text{O}_2\text{(g)} \rightarrow \text{CO}_2\text{(g)} \quad \Delta H_2 = -393\text{ kJ}$
- $\text{CH}_4\text{(g)} + 2\text{O}_2\text{(g)} \rightarrow \text{CO}_2\text{(g)} + 2\text{H}_2\text{O(g)} \quad \Delta H_3 = -890\text{ kJ}$

Calculate the enthalpy change for the reaction:

This article aims to demystify the typical questions encountered within a Chemistry B thermochemistry packet, providing detailed explanations and insights to enhance understanding and confidence.

Understanding Chemistry B Thermochemistry: An Overview

Before diving into specific answers, it's essential to establish a foundational understanding of what thermochemistry entails within the context of Chemistry B. Thermochemistry focuses on the study of heat changes that occur during chemical reactions and physical transformations. It bridges concepts from physics and chemistry, emphasizing energy transfer, enthalpy, entropy, and the laws of thermodynamics.

The Significance of Thermochemistry in Chemistry B

- Predicting Reaction Outcomes: Understanding whether a reaction absorbs or releases heat helps in predicting spontaneity.
- Energy Calculations: Quantifying energy changes allows students to calculate enthalpy (ΔH), entropy (ΔS), and Gibbs free energy (ΔG).
- Real-world Applications: Thermochemistry principles underpin fields like engineering, environmental science, and materials development.

Key Concepts in Thermochemistry

A robust grasp of several core concepts is essential for solving thermochemistry problems accurately. These include:

- Enthalpy (ΔH)
 - Represents the heat content of a system at constant pressure.
 - Positive ΔH indicates an endothermic process (absorbs heat).
 - Negative ΔH signifies an exothermic process (releases heat).
- Calorimetry
 - The experimental measurement of heat transfer during a chemical or physical change.
 - Involves devices like calorimeters to measure temperature changes.
- Hess's Law
 - States that the total enthalpy change for a reaction is the sum of enthalpy changes for individual

steps.

- Useful for calculating ΔH for reactions where direct measurement is difficult.
- Standard Enthalpy of Formation (ΔH°_f)
 - The change in enthalpy when one mole of a compound forms from its elements in their standard states.
 - Used as reference points for calculating other enthalpy changes.

Typical Questions in a Chemistry B Thermochemistry Packet

Students working through thermochemistry packets often encounter various question types, such as conceptual questions, calculation problems, and application-based scenarios. Here, we will break down common question formats and provide detailed answers.

- Calculating Enthalpy Changes from Heat Measurements

Question Example:

A 50.0 g sample of ice at 0°C is melted in a calorimeter. If the temperature of the calorimeter increases from 0°C to 5°C during the process, and the calorimeter's heat capacity is $100 \text{ J/}^\circ\text{C}$, what is the enthalpy change of melting the ice?

Answer Breakdown:

- Step 1: Calculate the heat absorbed by the calorimeter:

$$q_{\text{calorimeter}} = C_{\text{calorimeter}} \times \Delta T = 100 \text{ J/}^\circ\text{C} \times 5^\circ\text{C} = 500 \text{ J}$$

- Step 2: Recognize that the heat absorbed by the calorimeter is equal in magnitude to the heat required to melt the ice (assuming no heat loss).

Therefore, $q_{\text{ice}} = 500 \text{ J}$

- Step 3: Convert heat to molar basis:

Number of moles of ice:

$$n(\text{Moles}) = \frac{50.0 \text{ g}}{18.015 \text{ g/mol}} \approx 2.78 \text{ mol}$$

- Step 4: Calculate ΔH for melting per mole:

$$\Delta H_{\text{melt}} = \frac{q_{\text{ice}}}{n(\text{moles})} = \frac{500 \text{ J}}{2.78 \text{ mol}} \approx 180 \text{ J/mol}$$

Conclusion:

The enthalpy of fusion (melting) for ice under these conditions is approximately +180 J/mol, indicating an endothermic process.

- Applying Hess's Law to Find Enthalpy Changes

Question Example:

Given the following reactions:

Calculate the ΔH for the formation of CO from C and O₂.

Answer Breakdown:

- Step 1: Recognize that the formation of CO from C and O₂ can be related to the given reactions.

- Step 2: Write the target reaction:

- Step 3: Reverse reaction 2 to get:

- Step 4: Add this reversed reaction to reaction 1:

plus

- Step 5: The sum yields:

- Step 6: Simplify to the target reaction:

- Step 7: Sum the enthalpy changes:

$$\Delta H = -393.5 \text{ kJ} + 110.5 \text{ kJ} = -283 \text{ kJ}$$

Result:

The enthalpy change for forming CO from C and O₂ is -283 kJ.

- Interpreting Standard Enthalpy of Formation Data

Question Example:

Using standard enthalpies of formation, determine the enthalpy change for the reaction:

Given:

- ΔH°_f (CH₄) = -74.8 kJ/mol
- ΔH°_f (CO₂) = -393.5 kJ/mol
- ΔH°_f (H₂O, liquid) = -285.8 kJ/mol

Answer Breakdown:

- Step 1: Write the enthalpy change formula:

$$\Delta H^\circ_{\text{rxn}} = [\sum \Delta H^\circ_f (\text{products})] - [\sum \Delta H^\circ_f (\text{reactants})]$$

- Step 2: Calculate the total for products:

$$(-393.5) + 2 \times (-285.8) = -393.5 - 571.6 = -965.1 \text{ kJ}$$

- Step 3: Calculate the total for reactants:

$$-74.8 + 2 \times 0 \text{ (since O}_2 \text{ in its elemental form has } \Delta H^\circ_f = 0) = -74.8 \text{ kJ}$$

- Step 4: Find the $\Delta H^\circ_{\text{rxn}}$:

$$-965.1 - (-74.8) = -890.3 \text{ kJ}$$

Conclusion:

The reaction releases approximately 890.3 kJ of energy, indicating an exothermic process.

Common Pitfalls and Tips for Success

- Unit Consistency: Always ensure energy units are consistent (Joules vs. kilojoules). Convert as necessary.
- Significance of Signs: Remember that negative ΔH signifies exothermic reactions, and positive indicates endothermic.
- Data Accuracy: Use reliable standard enthalpy of formation values and verify your sources.

Question 1: What is the enthalpy change of the reaction if 50.0 g of water (specific heat = 4.18 J/g°C) is heated from 25°C to 75°C?

Answer:

- Calculate the heat absorbed (q):

$$q = m \times c \times \Delta T$$

$$q = 50.0 \text{ g} \times 4.18 \text{ J/g}^\circ\text{C} \times (75^\circ\text{C} - 25^\circ\text{C})$$

$$q = 50.0 \times 4.18 \times 50$$

$$q = 50.0 \times 209$$

$$q = 10,450 \text{ J}$$

- Since this is a heating process with no chemical reaction involved, the enthalpy change (ΔH) for the process is 10,450 J (or 10.45 kJ).

Question 2: Using Hess's Law, determine the enthalpy change for the reaction:

Given:

- $\text{C} + \text{O}_2 \rightarrow \text{CO}_2$, $\Delta H = -393.5 \text{ kJ}$
- $2\text{H}_2 + \text{O}_2 \rightarrow 2\text{H}_2\text{O}$, $\Delta H = -571.6 \text{ kJ}$
- $\text{CH}_4 + 2\text{O}_2 \rightarrow \text{CO}_2 + 2\text{H}_2\text{O}$, $\Delta H = -890.3 \text{ kJ}$

Answer:

- Rearrange the reactions to find the target:

The target reaction can be derived as:

\[

\]

- Use Hess's Law:

\[

$$\Delta H_{\text{target}} = \Delta H_{\{1\}} + \Delta H_{\{2\}} + \text{appropriate adjustments}$$

\]

- But since the given reactions are:

- Reverse reaction 3:

\[

\]

- Add reactions 1, 2, and the reversed 3:

\[

\]

\[

\]

\[

\]

- Sum:

\[

\]

- Cancel common terms:

- CO_2 on both sides cancels.

- $2\text{H}_2\text{O}$ cancels.

Remaining:

\[

\]

- Sum the enthalpy changes:

$\Delta H = -393.5 + (-571.6) + 890.3 = -393.5 - 571.6 + 890.3 = -75.8 \text{ kJ}$

Therefore, ΔH for the formation of methane from carbon and hydrogen is approximately -75.8 kJ.
