design example for secant pile wall is an essential process in geotechnical and civil engineering projects, especially when constructing deep excavations, retaining structures, or underground facilities. Secant pile walls are widely appreciated for their strength, flexibility, and minimal environmental impact. This article provides a comprehensive design example for a secant pile wall, illustrating the steps, calculations, and considerations involved in developing an effective and safe retaining structure.

Introduction to Secant Pile Walls

Secant pile walls consist of overlapping reinforced concrete piles arranged in a closely spaced pattern, typically in a grid. The primary purpose of this structure is to retain soil and groundwater, provide stability to excavations, and serve as a permanent or temporary retaining mechanism.

Key Features of Secant Pile Walls

- Composed of primary and secondary piles arranged alternately.
- Overlapping piles create a continuous, impermeable barrier.
- Suitable for urban areas due to minimal vibration during construction.
- Can be designed as permanent or temporary structures.

Basic Design Parameters

Before delving into the detailed design example, it is crucial to understand the fundamental parameters that influence the design of a secant pile wall:

- Site conditions: Soil type, groundwater level, and existing loads.
- Wall geometry: Depth, thickness, and layout.
- Loading conditions: Soil pressure, surcharge loads, seismic considerations.
- Material properties: Concrete strength, reinforcement specifications.
- Construction constraints: Space limitations, construction sequence.

Step-by-Step Design Example

This section walks through an example of designing a secant pile wall for a hypothetical project involving a deep excavation in a clayey soil profile.

- Site and Geotechnical Data

Suppose the project site has the following characteristics:

- Soil profile:
- Surficial clay: 0?5 m
- Firm clay: 5?15 m
- Dense gravelly sand (bedrock): below 15 m
- Groundwater level: at 2 m below ground surface
- Design depth of excavation: 12 m
- Surcharge load: 10 kPa (e.g., existing structures)

- Selection of Pile Layout and Dimensions

Based on the site conditions, the initial assumptions are:

- Pile diameter: 600 mm (common for such applications)
- Center-to-center spacing: 1.0 m (to ensure overlapping)
- Number of piles: Determined by the length and spacing; for a 20 m long wall, approximately 20 piles are needed.

- Structural Design of Piles

a. Axial Capacity Calculation

The axial capacity of a pile depends on the soil-pile interface and the concrete strength.

- Concrete strength (f_c): 40 MPa
- Reinforcement ratio: Standard for secant piles, around 1%
- Ultimate bearing capacity: Calculated using empirical formulas or geotechnical data.

Suppose the ultimate axial capacity per pile is estimated at 2000 kN.

b. Reinforcement Details

Reinforcement cages are designed to withstand bending moments and shear forces during

construction and service life.

- Structural Stability Analysis

a. Slope Stability and Overturning

Calculate the moments and forces acting on the wall, considering:

- Lateral earth pressure
- Hydrostatic pressure of groundwater
- Surcharge loads

Using Rankine's or Coulomb's earth pressure theory, the active and passive earth pressures at different depths are computed.

b. Lateral Earth Pressure Calculations

Approximate the lateral earth pressure using Rankine's theory:

\[

$$\sigma_h = K_a \times \sigma_v$$

\]

where:

- (K_a) = active earth pressure coefficient, depending on the soil friction angle
- (σ_v) = vertical effective stress

Assuming:

- Friction angle $(\phi) = 30^\circ$
- Poisson's ratio and other parameters are incorporated into calculations.

- Structural Design of the Wall

Design the reinforcement layout ensuring:

- Adequate bending and shear capacity
- Crack control
- Connection details

The wall can be designed as a cantilever or anchored, depending on the excavation depth and lateral loads.

- Water Tightness and Sealing

To ensure groundwater control:

- Overlap of piles must be sufficient (minimum 50 mm)
- Use of waterproof concrete or sealants
- Consideration of drainage provisions

- Construction Sequence

A typical construction process:

- Drilling primary piles to the designed depth.
- Reinforcement cage installation in primary piles.
- Concrete pouring to form the primary wall.
- Drilling secondary piles in between primary piles, overlapping with primary.
- Reinforcement and concreting of secondary piles.
- Excavation behind the completed secant wall, with dewatering as needed.
- Monitoring and adjustments during construction.

Design Calculations Summary

| Parameter | Value |

|-----|-----|

| Pile diameter | 600 mm |

- | Spacing | 1.0 m |
- | Number of piles | 20 |
- | Excavation depth | 12 m |
- | Groundwater level | 2 m below ground surface |
- | Soil type | Clay and gravelly sand |
- | Soil shear angle | 30° |
- | Concrete strength | 40 MPa |
- | Estimated pile capacity | 2000 kN per pile |

The lateral earth pressure at the base:

$$\sigma_h = K_a \times \sigma_v$$

with

$$K_a = \tan^2(45^\circ - \phi/2) \approx 0.33$$

and

$$\sigma_v = \gamma \times z$$

where γ = unit weight (~18 kN/m³ for clay).

At 12 m depth:

\[

$$\sigma_v = 18 \times 12 = 216, \text{ kPa}$$

\]

Thus,

\[

$$\sigma_h = 0.33 \times 216 \approx 71, \text{ kPa}$$

\]

The total lateral force acting on the wall per unit length:

\[

$$P = \frac{1}{2} \times \sigma_h \times H = 0.5 \times 71 \times 12 \approx 426, \text{ kPa}$$

\]

This force is distributed among the piles, and the reinforcement must be designed to resist these lateral loads.

Considerations for Effective Design

- Overlapping Piles: Ensuring sufficient overlap for waterproofing and structural integrity.
- Reinforcement Detailing: Proper anchorage and spacing to prevent cracking.
- Groundwater Control: Implementing dewatering and waterproofing measures.
- Construction Methodology: Choosing appropriate drilling and concreting techniques to minimize disturbance.
- Monitoring: Installing sensors during construction to observe movements and pressures.

Conclusion

Designing a secant pile wall requires a systematic approach that integrates geotechnical data, structural calculations, and construction practices. The example provided demonstrates the typical

steps involved?from understanding site conditions and selecting pile dimensions to analyzing earth pressures and detailing reinforcement. A well-designed secant pile wall ensures the safety and stability of deep excavations, minimizes environmental impact, and provides a durable barrier suitable for various construction needs.

By following these principles and calculations, engineers can develop effective secant pile wall designs tailored to specific project requirements, ensuring both safety and longevity in challenging geotechnical environments.

Design example for secant pile wall: A comprehensive guide to modern retaining wall engineering

In the realm of geotechnical engineering, retaining walls play a pivotal role in controlling earth pressures and stabilizing slopes. Among the various types, the secant pile wall has gained prominence due to its robustness, adaptability, and minimal environmental footprint. This article delves into a detailed design example for a secant pile wall, illustrating the step-by-step process engineers undertake?from site investigation to final detailing?to ensure stability, safety, and cost-effectiveness. Whether you're a seasoned geotechnical engineer or a student seeking practical insights, this comprehensive guide aims to clarify the intricacies involved in designing a secant pile wall.

Understanding the Secant Pile Wall: An Overview

Before exploring the design process, it?s essential to understand what a secant pile wall entails.

What Is a Secant Pile Wall?

A secant pile wall is a type of underground retaining structure constructed by overlapping reinforced concrete piles. Unlike contiguous bored piles that are placed side-by-side with minimal gaps, secant piles are arranged with overlapping sections, creating a continuous barrier. This overlapping forms a strong, monolithic structure capable of resisting lateral earth and water pressures.

Applications and Advantages

- Applications:
- Retaining walls for deep excavations
- Ground stabilization in urban environments
- Waterfront quay walls
- Underground structures and basements

- Advantages:
- High structural integrity due to overlapping piles
- Reduced seepage through joints
- Suitable for complex and urban sites
- Can be constructed with minimal vibration

Site Investigation and Data Collection

A robust design begins with thorough site investigation. For our example, consider a hypothetical urban construction site requiring a secant pile wall to facilitate a deep excavation of a 10-meter depth.

Geotechnical Data

- Soil Profile:
- Topsoil: 1 m
- Silty Clay: 4 m
- Sandy Gravel: 5 m
- Bedrock: Not encountered

- Soil Properties:
- Silty Clay: Cohesion (c) = 15 kPa, Friction angle (ϕ) = 20° , unit weight (γ) = 18 kN/m³
- Sandy Gravel: γ = 20 kN/m³

Water Conditions

- Groundwater table located at 2 meters below ground level
- Potential for seepage and water pressure exerted on the wall

Load Conditions

- Earth pressures based on the soil properties
- Hydrostatic pressure due to groundwater
- Live and dead loads from nearby structures

Structural and Geotechnical Design Principles

Designing a secant pile wall involves multiple considerations:

- Structural stability: Overturning, sliding, and bearing capacity
- Geotechnical stability: Earth and water pressures
- Construction constraints: Pile spacing, overlap, and reinforcement
- Durability: Corrosion protection and waterproofing

Step-by-Step Design Example

Step 1: Determining the Wall Geometry and Pile Arrangement

Pile Diameter and Spacing:

- Typical pile diameter: 600 mm to 900 mm
- Spacing: Usually 1.5 to 2 times the diameter for overlapping piles
- For this example:
 - Diameter (D): 800 mm (0.8 m)
 - Center-to-center spacing: 1.2 m (including overlaps)

Number of Piles:

- Total length of wall: 10 m (depth of excavation)
- Number of piles:
 - Based on wall length; assume a wall length of 20 m
 - Pile count: Approximately 17 piles (spacing 1.2 m)

Step 2: Preliminary Structural Design of Piles

Reinforcement and Concrete:

- Reinforced concrete piles with:
 - Longitudinal reinforcement: 16 mm bars
 - Spiral reinforcement to confine the concrete
 - Concrete strength: C30 (compressive strength of 30 MPa)

Overlapping Sections:

- Piles are constructed with a minimum overlap of 300 mm to ensure monolithic behavior
- Overlap length: 0.3 m, which is critical for load transfer and stability

Step 3: Earth and Water Pressure Calculations

Using Rankine's or Coulomb's theory, calculate lateral earth pressure:

- Active earth pressure (K_a):

$$K_a = \tan^2 \left(45^\circ - \frac{\phi}{2} \right)$$

For $\phi = 20^\circ$,

$$K_a \approx 0.33$$

- Hydrostatic pressure:

$$p_{\text{water}} = \gamma_{\text{water}} \times h$$

Assuming saturated soil and water at 2 m,

$$p_{\text{water}} = 9.81 \text{ kN/m}^3 \times 2 \text{ m} \approx 19.6 \text{ kPa}$$

- Total lateral pressure at depth h :

$$p_{\text{total}} = (K_a \times \gamma_{\text{soil}} \times h) + p_{\text{water}}$$

At the base ($h=10$ m):

$$p_{\text{soil}} = 0.33 \times 18 \times 10 = 59.4 \text{ kPa}$$

$$p_{\text{water}} = 19.6 \text{ kPa}$$

Total pressure at base:

$$p_{\text{total}} = 59.4 + 19.6 = 79 \text{ kPa}$$

The pressure varies linearly with depth.

Step 4: Structural Stability Checks

Overturning Moment:

- Calculate the resultant lateral force (area under pressure diagram):

$$(P = \frac{1}{2} \times p_{\text{average}} \times \text{height})$$

- Approximate (p_{average}) :

$$(p_{\text{average}} = \frac{p_{\text{top}} + p_{\text{bottom}}}{2})$$

(p_{top}) : negligible, as pressure at surface is near zero

(p_{bottom}) : 79 kPa

Average pressure: approximately 40 kPa

Total force:

$$(P = 40 \text{ kPa} \times 20 \text{ m} \times 10 \text{ m} = 8,000 \text{ kN})$$

Moment about the base:

$$(M = P \times \frac{\text{height}}{3} = 8,000 \times \frac{10}{3} \approx 26,667 \text{ kNm})$$

Resisting Moment:

- Due to the weight of the wall and piles (assumed concrete density $\gamma_c = 24 \text{ kN/m}^3$):

Cross-sectional area of piles per meter length:

$$(A_{\text{pile}} = \pi \times (0.4)^2 \approx 0.5 \text{ m}^2)$$

Total weight per meter:

$$(W = 0.5 \times 24 = 12 \text{ kN})$$

Resisting moment:

$$(M_{\text{resist}} = W \times \frac{L^2}{2})$$

- For 17 piles over 20 m:

Total weight:

$$(12 \text{ kN} \times 20 \text{ m} \times 17 \approx 4,080 \text{ kN})$$

Assuming the centroid at mid-height:

Resisting moment:

$$(4,080 \times 10 = 40,800 \text{ kNm})$$

This exceeds the overturning moment, indicating stability.

Step 5: Checking Sliding and Bearing Capacity

- Sliding resistance:

Assuming a friction coefficient $\mu = 0.6$:

$$(R_s = \text{Normal force} \times \mu)$$

- Bearing capacity:

Ensure that the pile footings are designed to withstand the vertical loads without punching or shear failure.

Construction Considerations

Designing a secant pile wall is only part of the process; construction methodology impacts the final performance.

Construction Sequence:

- Boring and reinforcement placement:
- Sequential boring of each pile with reinforcement cages inserted
- Pouring concrete:
- Continuous pouring to ensure overlapping and monolithic behavior
- Overlap management:
- Ensuring minimum 0.3 m overlap for structural integrity
- Waterproofing:
- Applying waterproof membranes or coatings to prevent seepage
- Curing and quality control:
- Adequate curing to achieve desired strength
- Non-destructive testing (e.g., core sampling) to verify construction quality

Quality Assurance:

- Monitoring pile dimensions
- Checking reinforcement placement
- Conducting load tests on selected piles

Final Design Verification and Documentation

After completing the calculations and construction, finalize the design documentation:

- Structural drawings: detailing pile dimensions, reinforcement, overlaps
- Specifications: concrete grades, reinforcement types, waterproofing
- Calculation reports: including earth pressure calculations, stability checks
- Construction notes: sequence, safety measures, quality control procedures

Conclusion

The design example for a secant pile wall illustrates a methodical approach that combines geotechnical understanding with structural engineering principles. From initial site investigations and soil characterization to detailed calculations and construction planning, each step is crucial to ensure the wall performs its intended function safely and durably. Modern engineering practices emphasize meticulous design, rigorous stability checks,

Question What are key considerations when designing a secant pile wall as a retaining structure? Key considerations include soil conditions, groundwater levels, load requirements, pile spacing and diameter, reinforcement details, construction sequence, and stability against overturning, sliding, and bearing capacity failure. How do you determine the appropriate pile spacing in a secant pile wall design? Pile spacing is typically determined based on the desired wall stiffness, wall stability, and load transfer. Common practice involves spacing between 1.5 to 3 times the pile diameter, ensuring sufficient overlap for structural integrity and limiting deflections. What are common reinforcement details in secant pile wall designs? Reinforcement typically includes longitudinal bars within each pile, overlapping reinforcement between adjacent piles to ensure monolithic behavior, and sometimes tie-bars or cross ties to enhance stability and reduce deformation. The reinforcement is designed based on load requirements and soil conditions. How does soil type influence the design example of a secant pile wall? Soil type impacts pile diameter, spacing, reinforcement, and construction method. For example, stiff clays may require less reinforcement, while sandy or loose soils may necessitate larger piles, increased overlap, and specialized reinforcement details to ensure stability and minimize settlement. Can you provide a basic example of a secant pile wall design calculation? A simplified example involves selecting pile diameter (e.g., 600mm), determining pile spacing (e.g., 900mm), calculating the overlap (e.g., 200mm), and verifying stability against sliding and overturning using soil parameters and load considerations. Reinforcement is then designed to withstand axial and lateral forces, ensuring the wall's structural safety.

Design concrete foundation examples using eurocode 2

design concrete foundation examples using eurocode 2 is a fundamental aspect of structural engineering that ensures safety, durability, and compliance with European standards. Eurocode 2 (EN 1992-1-1) provides comprehensive guidelines for the design of concrete structures, including foundations, to optimize performance under various loading conditions. Proper understanding and application of these standards are essential for engineers aiming to develop efficient, reliable, and

code-compliant foundation solutions. In this article, we will explore detailed examples of designing concrete foundations based on Eurocode 2, covering different types of foundations, key design principles, and practical considerations.

Overview of Eurocode 2 for Concrete Foundation Design

Eurocode 2 (EN 1992-1-1) is part of the European Standard suite that governs the design of concrete structures. Its main objectives are to ensure structural safety, serviceability, and durability. When designing concrete foundations, Eurocode 2 provides rules for:

- Material properties and testing
- Structural analysis and load combinations
- Design of reinforcement
- Crack control
- Durability considerations

Understanding these aspects is crucial for developing foundation solutions that meet regulatory requirements and perform effectively throughout their lifespan.

Types of Concrete Foundations Covered by Eurocode 2

Eurocode 2 applies to various foundation types, including:

1. Strip Foundations

Used primarily for load-bearing walls, strip foundations are continuous strips of concrete that support load-bearing walls and distribute loads over a wider area.

2. Raft (Mat) Foundations

A large concrete slab supporting multiple columns or walls, suitable for poor soil conditions or heavy loads.

3. Pad Foundations

Isolated foundations supporting individual columns or piers, designed to transfer concentrated loads.

4. Pile Foundations

Deep foundations used when shallow foundations are insufficient, transferring loads through piles

into stable soil layers.

Each foundation type requires specific design considerations, which we will explore through examples.

Design Principles for Concrete Foundations per Eurocode 2

Before delving into examples, it's essential to understand the core principles guiding foundation design under Eurocode 2:

- **Load Analysis:** Consider all relevant loads, including dead loads, live loads, imposed loads, and environmental factors, combined according to EN 1990 principles.
- **Soil-Structure Interaction:** Evaluate soil bearing capacity, settlement, and stability to ensure foundation adequacy.
- **Material Selection:** Use concrete and reinforcement grades compliant with Eurocode specifications, considering durability and environmental exposure.
- **Reinforcement Design:** Calculate reinforcement requirements to resist bending, shear, and axial forces, ensuring ductility and safety.
- **Serviceability and Crack Control:** Limit crack widths and deflections to acceptable levels based on serviceability criteria.
- **Durability:** Design for resistance against environmental effects, such as freeze-thaw cycles, corrosion, and chemical attack.

Concrete Foundation Design Examples Using Eurocode 2

In this section, we present detailed examples illustrating the application of Eurocode 2 standards to different foundation types. Each example includes assumptions, calculations, and design considerations.

Example 1: Designing a Strip Foundation for a Load-Bearing Wall

Project Overview:

- Building load: 150 kN/m (per meter length of wall)
- Soil bearing capacity: 100 kPa
- Width of strip foundation: To be determined
- Concrete grade: C20/25 ($f_{ck} = 20$ MPa)
- Reinforcement: B500B

Step 1: Calculate the required foundation width

Using Eurocode 2, the ultimate bearing capacity (q_u) is given by:

$$q_u = \text{soil bearing capacity} \times \text{partial safety factor}$$

Assuming a partial safety factor for soil ($\gamma_s = 1.25$):

$$q_{allow} = \frac{100 \text{ kPa}}{1.25} = 80 \text{ kPa}$$

The foundation must distribute the load without exceeding the soil strength:

$$b = \frac{N_{ed}}{q_{allow} \times L}$$

Where:

- ($N_{ed} = 150 \text{ kN/m}$)
- (L) is the length of the foundation (assume 1 m for per meter calculation)

Rearranged:

$$b = \frac{150 \text{ kN}}{80 \text{ kPa} \times 1 \text{ m}} = \frac{150 \text{ kN}}{80 \text{ kN/m}^2} = 1.875 \text{ m}$$

However, such a large width is impractical. To optimize, incorporate safety and settlement considerations, and choose a standard width, say 0.5 m, then verify bearing capacity adequacy.

Step 2: Check bearing capacity with chosen width

Total load per meter:

$$N_{ed} = 150 \text{ kN}$$

Ultimate bearing capacity:

$$q_u = c \times N_c + \sigma_0 \times N_q + 0.5 \times \gamma_b \times B \times N_{\gamma}$$

Assuming:

- cohesion $(c = 0)$ (cohesionless soil)
- effective stress (σ_0) at foundation level
- use Eurocode 7 charts or formulas for detailed calculation

The simplified approach suggests that a 0.5 m width foundation is sufficient if soil conditions are favorable.

Step 3: Reinforcement Design

Calculate bending moments and shear forces based on load distribution, then determine reinforcement:

- Use Eurocode 2 formulas for bending reinforcement, considering the concrete's characteristic strength.
- Check crack widths and serviceability limits.

Step 4: Durability and Detailing

- Cover concrete minimum 50 mm for durability.
- Use reinforcement detailing per EN 1992-1-1 recommendations.

Example 2: Designing a Raft Foundation for a Small Office Building

Project Overview:

- Total load: 1,200 kN
- Building dimensions: 10 m x 15 m
- Soil bearing capacity: 150 kPa
- Concrete grade: C30/37 ($f_{ck} = 30$ MPa)
- Reinforcement: B500B

Step 1: Determine Foundation Thickness

Assuming a uniform load and aiming for minimal settlement, choose a thickness (h) based on Eurocode 2 guidelines:

$$h = \frac{N_{total}}{q_{allow} \times B \times L}$$

Calculate:

$$q_{allow} = \frac{150 \text{ kPa}}{1.35} \approx 111 \text{ kPa}$$

Total area:

$$A_{foundation} = B \times L$$

Assuming a 0.5 m thick slab:

$$\text{Design load per unit area} = \frac{1,200 \text{ kN}}{10 \text{ m} \times 15 \text{ m}} = 8 \text{ kPa}$$

Check if the foundation can support this load with the chosen thickness and reinforcement.

Step 2: Reinforcement Calculation

- Bending moments and shear forces are computed for the slab.
- Design reinforcement for flexure and shear per EN 1992-1-1.

Step 3: Detailing and Durability

- Reinforcement spacing, cover, and anchorage are specified.
- Consider environmental exposure for durability.

Example 3: Designing a Pile Foundation Using Eurocode 2 Principles

Project Overview:

- Load per pile: 500 kN
- Number of piles: 4
- Soil bearing capacity at pile tip: 300 kPa
- Pile type: Concrete bored piles
- Concrete grade: C25/30

Step 1: Pile Diameter and Length

Using Eurocode 2, the pile cross-section is designed to resist axial loads and moments:

- Diameter (D) typically ranges between 0.4 m and 0.6 m.
- Length is determined by soil conditions and load transfer capacity.

Design checks include:

- Pile axial capacity:

$$N_{allow} = A_{pile} \times q_c$$

Where (q_c) is the characteristic soil strength at pile tip.

- Concrete and reinforcement design to resist axial and bending forces.

Step 2: Reinforcement Detailing

- Ensure reinforcement for axial load capacity and possible moments.
- Use Eurocode 2 formulas to determine reinforcement ratios and detailing.

Practical Considerations in Concrete Foundation Design Using Eurocode 2

When applying Eurocode 2 standards to real-world foundation design, engineers should also consider:

- **Site Investigation:** Accurate soil testing and analysis to determine bearing capacity, settlement potential, and soil type.

- **Load Path and Distribution:** Proper load transfer mechanisms to prevent

Design Examples Using Eurocode 2

Let's explore detailed examples illustrating the design of various foundation types.

Example 1: Isolated Concrete Pad Foundation for a Column

Project Data:

- Column load (axial): 3000 kN
- Column dimensions: 0.3 m × 0.3 m
- Soil bearing capacity (allowable): 150 kPa
- Concrete class: C25/30
- Reinforcement: Tension reinforcement as per design

Design Steps:

- Determine Foundation Size
- Ultimate bearing capacity (q_{ult}): Use simplified formulas or Terzaghi's method.
- Required bearing area (A_f):

$$A_f = \frac{N_{Ed}}{q_{allow}} = \frac{3000 \text{ kN}}{150 \text{ kPa}} = 20 \text{ m}^2$$

- Foundation dimensions: To keep the foundation square:

$$B = \sqrt{A_f} \approx 4.47 \text{ m}$$

- Design dimensions: For practicality, choose $B = 4.5 \text{ m}$.

- Check Bending and Shear

- Calculate bending moments: For a uniformly loaded foundation, approximate considering load eccentricity.

- Design reinforcement: Use Eurocode 2 formulas for tension reinforcement, ensuring minimum

reinforcement ratios.

- Serviceability Checks

- Crack width: Ensure reinforcement spacing and concrete cover limit crack widths.
- Deflections: Check for overstress or excessive settlement.

- Detail Reinforcement

- Main reinforcement: Provide top and bottom bars, with anchorage lengths per Eurocode 2.
- Distribution reinforcement: To control cracking, especially near edges.

Summary: This simplified example demonstrates the initial sizing based on load and soil capacity, followed by detailed reinforcement design following Eurocode 2 directives.

Example 2: Strip Foundation Supporting a Load-Bearing Wall

Project Data:

- Wall load: 200 kN/m length
- Soil bearing capacity: 120 kPa
- Design load (factored): $1.35 \times \text{dead} + 1.5 \times \text{live}$
- Foundation width: To be determined

Design Process:

- Calculate Foundation Width

$$B = \frac{Q_{\text{factored}}}{q_{\text{allow}}}$$

Assuming the load per unit length is 200 kN/m, and the soil capacity is 120 kPa:

$$B = \frac{200 \, \text{kN/m}}{120 \, \text{kPa}} = \frac{200 \, \text{kN/m}}{120 \, \text{kN/m}^2} \approx 1.67 \, \text{m}$$

- Choose $B = 1.7$ m for simplicity.
- Determine Reinforcement
 - Calculate bending moments: For a uniformly distributed load, use standard formulas.
 - Design reinforcement: Ensure the reinforcement area satisfies Eurocode 2 minimum requirements, typically at least 0.2% of the cross-sectional area.
- Check for Shear and Stability
 - Shear capacity: Verify concrete shear capacity and provide shear reinforcement if necessary.
 - Overturning and sliding: Confirm foundation's stability against lateral forces.
- Durability and Detailing
 - Concrete cover: Maintain minimum cover as per Eurocode 2.
 - Reinforcement detailing: Use proper anchorage, lap lengths, and spacing.

Summary: This example highlights the importance of considering load distribution, soil capacity, and reinforcement detailing in strip foundation design under Eurocode 2.

Durability and Serviceability Aspects in Foundation Design

Designing concrete foundations isn't solely about strength; durability and serviceability are equally important:

- Durability considerations:
